Problem 1

Work through the lab in Section 9.6.1 of the course book.

Problem 2 (Book Ex.2)

We have seen that in p = 2 dimensions, a linear decision boundary takes the form $\beta_0 + \beta_1 X_1 + \beta_2 X_2 = 0$. We now investigate a non-linear decision boundary.

a) Sketch the curve

$$(1+X_1)^2 + (2-X_2)^2 = 4.$$

b) On your sketch, indicate the set of points for which

$$(1+X_1)^2 + (2-X_2)^2 > 4,$$

as well as the set of points for which

$$(1+X_1)^2 + (2-X_2)^2 \le 4.$$

c) Suppose that a classifier assigns an observation to the blue class if

$$(1+X_1)^2 + (2-X_2)^2 > 4$$
,

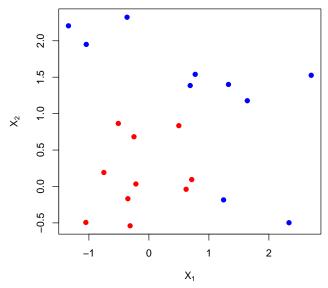

and to the red class otherwise. To what class is the observation (0,0) classified? (-1,1)? (2,2)? (3,8)?

d) Argue that while the decision boundary in (c) is not linear in terms of X_1 and X_2 , it is linear in terms of X_1, X_1^2, X_2 , and X_2^2 .

Problem 3

This problem involves plotting of decision boundaries for different kernels and it's taken from Lab video.

```
# code taken from video by Trevor Hastie
set.seed(10111)
x <- matrix(rnorm(40), 20, 2)
y <- rep(c(-1, 1), c(10, 10))
x[y == 1, ] <- x[y == 1, ] + 1
plot(x, col = y + 3, pch = 19, xlab = expression(X[1]), ylab = expression(X[2]))</pre>
```

```
dat = data.frame(x, y = as.factor(y))
```

(a) Plot the linear decision boundary of the svmfit model by using the function make.grid. Hint: Use the predict function for the grid points and then plot the predicted values {-1,1} with different colors.

R-hints:

```
library(e1071)
svmfit = svm(y ~ ..., ..., kernel = "...", cost = ..., scale = ...)
```

The following function may help you to generate a grid for plotting:

```
make.grid = function(x, n = 75) {
    # takes as input the data matrix x and number of grid points n in each direction
    # the default value will generate a 75x75 grid
    grange = apply(x, 2, range) # range for x1 and x2
    x1 = seq(from = grange[1, 1], to = grange[2, 1], length.out = n) # sequence from the lowest to the
    x2 = seq(from = grange[1, 2], to = grange[2, 2], length.out = n) # sequence from the lowest to the
    expand.grid(X1 = x1, X2 = x2) #create a uniform grid according to x1 and x2 values
}
```

- (b) On the same plot add the training points and indicate the support vectors.
- (c) The solutions to the SVM optimization problem is given by

$$\hat{\beta} = \sum_{i \in \mathcal{S}} \hat{\alpha}_i y_i x_i \ ,$$

where S is the set of the support vectors. From the svm() function we cannot extract $\hat{\beta}$, but instead we have access to $\operatorname{coef}_i = \hat{\alpha}_i y_i$, and $\hat{\beta}_0$ is given as rho. For more details see here.

Calculate the coeficients $\hat{\beta}_0$, $\hat{\beta}_1$ and $\hat{\beta}_2$. Then add the decisision boundary and the margins using the function abline() on the plot from (b).

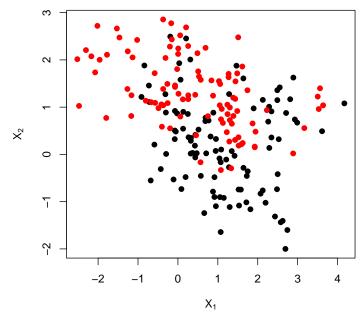

Problem 4

Now we fit an svm model with radial kernel to the following data taken from @ESL. Use cross-validation to find the best set of tuning parameters (cost C and γ). Using the same idea as in Problem 4a) plot the non-linear decision boundary, and add the training points. Furthermore if you want to create the decision

boundary curve you can use the argument decision.values=TRUE in the function predict, and then you can plot it by using the contour() function.

R-hints:

```
load(url("https://web.stanford.edu/~hastie/ElemStatLearn/datasets/ESL.mixture.rda"))
# names(ESL.mixture)
rm(x, y)
attach(ESL.mixture)
plot(x, col = y + 1, pch = 19, xlab = expression(X[1]), ylab = expression(X[2]))
```

```
dat = data.frame(y = factor(y), x)
```

To run cross-validation over a grid for (C, γ) , you can use a two-dimensional list of values in the ranges argument:

For the plot:

Problem 5 - optional (Book Ex. 7)

This problem involves the OJ data set which is part of the ISLR package.

- (a) Create a training set containing a random sample of 800 observations, and a test set containing the remaining observations.
- (b) Fit a support vector classifier to the training data using cost=0.01, with Purchase as the response and the other variables as predictors. Use the summary() function to produce summary statistics, and describe the results obtained.
- (c) What are the training and test error rates?
- (d) Use the tune() function to select an optimal cost. Consider values in the range 0.01 to 10.
- (e) Compute the training and test error rates using this new value for cost.
- (f) Repeat parts (b) through (e) using a support vector machine with a radial kernel. Use the default value for gamma.
- (g) Repeat parts (b) through (e) using a support vector machine with a polynomial kernel. Set degree=2.
- (h) Overall, which approach seems to give the best results on this data?
